Sense Pressure and EGM Signals

i. Determine Ventricular Systolic Pressure (VSP)

Calculate ePAD as the ventricular pressure measurement when the change in pressure over time (dp/dt) is at the maximum

Determine time between successive R waves (R-R Interval) from EGM signal

Determine Systolic Time Interval (STI) by measuring time from start of R wave to the time when dp/dt is at a maximum

$$DTI = R-R \text{ Interval} - STI$$

$$MPAP = \left[\left(\frac{DTI}{R-R \text{ Interval}} \right) \times ePAD \right] + \left[\left(\frac{STI}{R-R \text{ Interval}} \right) \times VSP \right]$$

Adjust, Initiate and/or Terminate Therapy Including Cardiac Resynchronization Therapy Based on the MPAP
